Diabetes Patients Dashboard

What the dashboard shows This dashboard summarizes data for 1,000 diabetes patients, including their average insulin level (155.34) and BMI (27.93). It also breaks patients down by alcohol consumption, BMI by age, diet quality, and a table of blood pressure values with how many patients fall into each reading.

Key insights or trends Most diabetic patients report no or low alcohol consumption, with “None” being the largest bar in the alcohol chart. Diet quality is mostly “Average,” with smaller but noticeable portions of patients in “Good” and “Poor” categories on the pie chart. BMI by age shows varying bar heights, suggesting BMI is not constant with age; some ages (around mid-20s) show higher BMI bars than others.

Important pattern/anomaly One standout pattern is that despite generally low alcohol consumption for most patients, BMI and insulin levels are still high (BMI near 28 and insulin 155+), which hints that factors other than alcohol—like diet quality or activity level—may be driving risk in this population.
